How the Keys Interact to Unlock Climate Gridlock

Temperatures are nearing Paris Agreement limits

Global fossil CO₂ emissions have been rising relentlessly

Global fossil CO₂ emissions: 34.8 ± 2 GtCO₂ in 2020, 53% over 1990
 Projection for 2021: 36.4 ± 2 GtCO₂, 4.9% [4.1%–5.7%] higher than 2020

© Global Carbon Project

The 2021 projection is based on preliminary data and modelling.

Source: [Friedlingstein et al 2021](#); [Global Carbon Project 2021](#)

Emissions by country

Global fossil CO₂ emissions are projected to increase by 4.9% [4.1%–5.7%] in 2021

The 2021 projections are based on preliminary data and modelling.

Source: [Friedlingstein et al 2021](#); [Global Carbon Project 2021](#)

Fossil CO₂ Emissions per capita

Worst-case scenarios avoided, but not on track for 1.5-2°C

2100 WARMING PROJECTIONS

Emissions and expected warming based on pledges and current policies

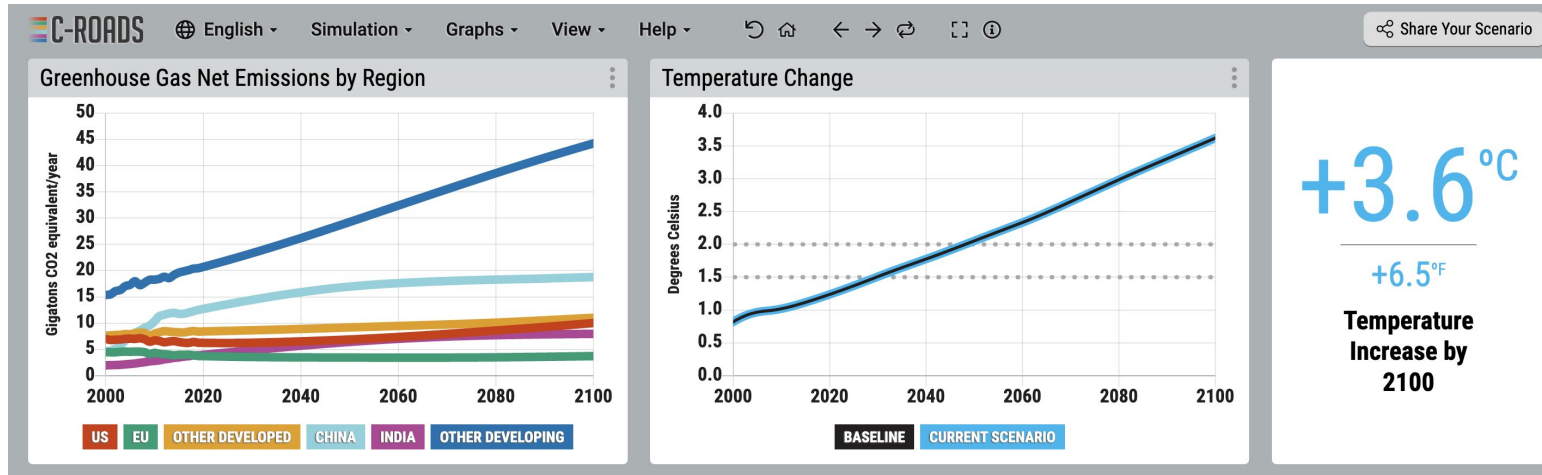

Nov 2021 update

Warming projected by 2100

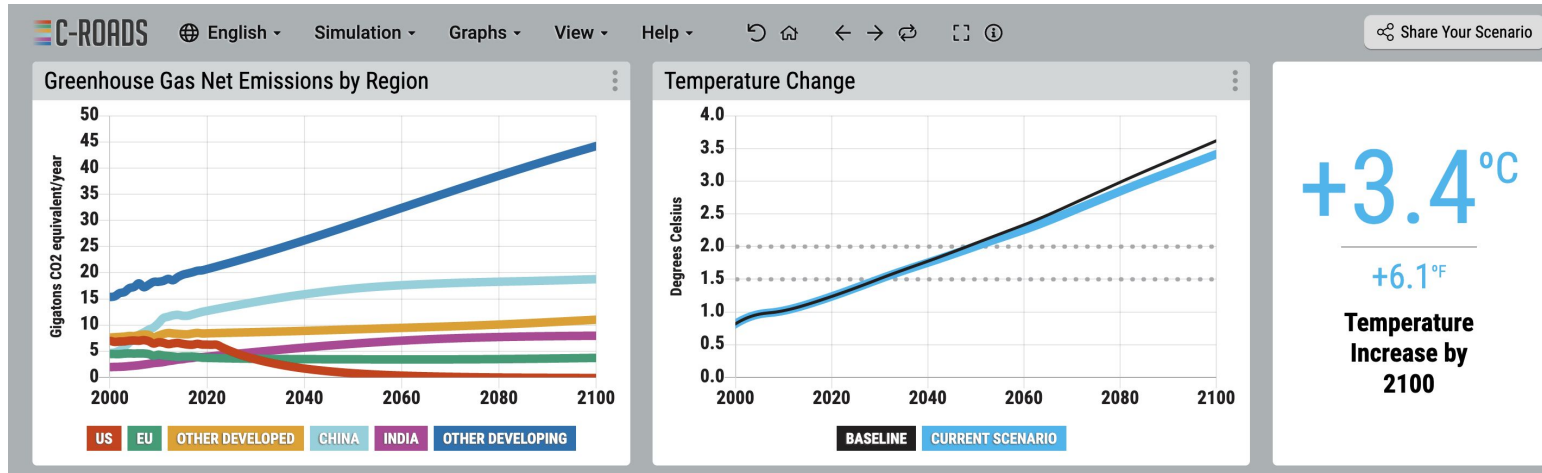

Net-zero in U.S. isn't enough

with U.S.
nearing
net-zero

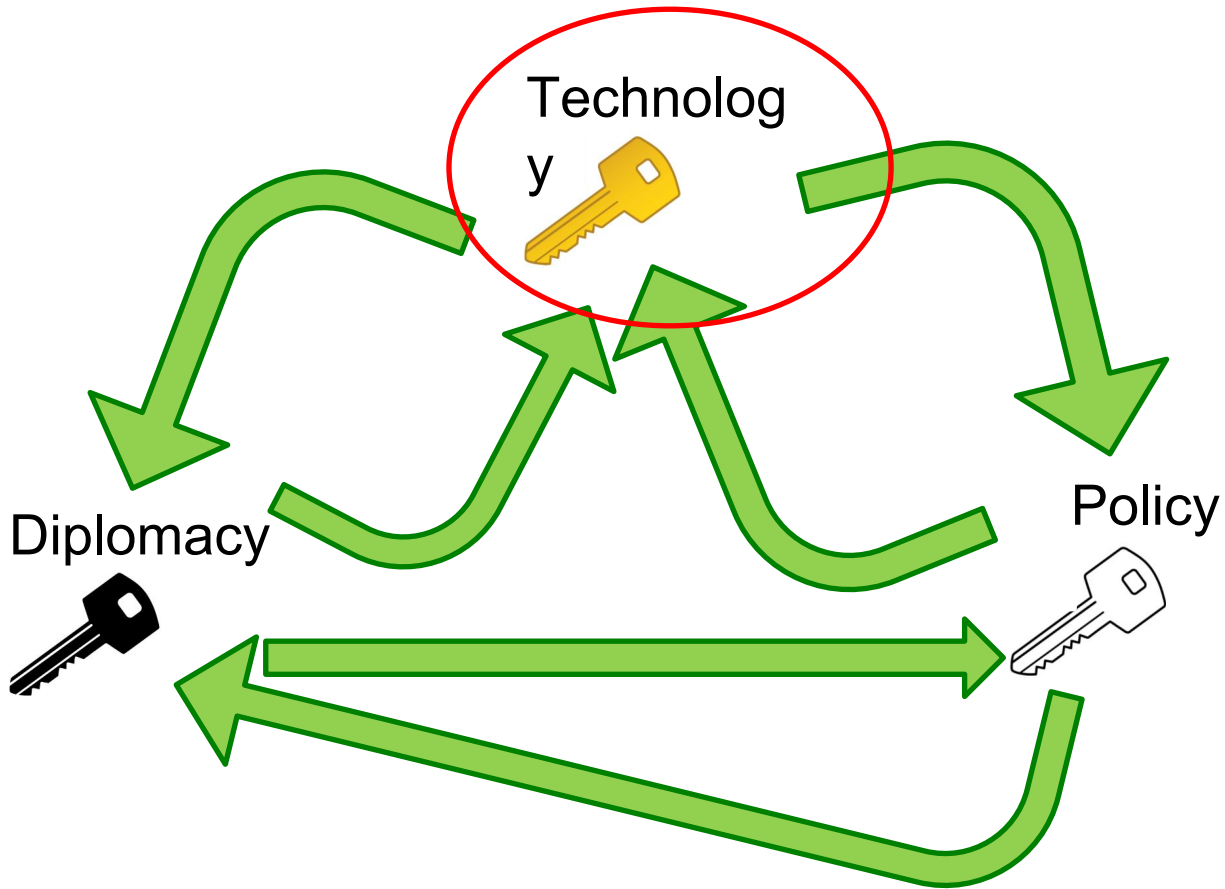

*Need to decarbonize energy affordably, reliably, and fast,
in ways that make it achievable globally*

Still, U.S. is crucial

- Most emissions historically and per-capita
- Largest economy and consumer market
- Leads in technology development
- Leading driver and barrier to diplomacy
- Need to make clean energy cheap here so it can be deployed elsewhere
 - Learning by doing drives down cost and improves performance

The Technology Key

Energy transitions historically have been slow

Energy consumption in the United States (1776-2040)
quadrillion Btu

Baseline projections expect fossil fuels to remain dominant

Energy production by source

AEO2022 Reference case

quadrillion British thermal units

Energy consumption by fuel

AEO2022 Reference case

quadrillion British thermal units

Some technology transitions have been incredibly fast

Outlooks are often wrong! E.g., overpredicted coal...

US Coal Generation – Actual and EIA Forecasts from 2010-2020

... And underpredicted renewables

**IEA New Solar Additions Per Year
Forecast vs History**

Even optimists failed to foresee cost declines in solar

Solar Costs Are Decades Ahead of Forecasts

Learning curves: Costs tend to fall ~18% per doubling in deployment

Solar prices on a log scale (each tick mark is a doubling)

Each tick mark is a doubling in global cumulative solar

Learning curves for the Model T

Price of Model T, 1909-1923 (Average list price in 1958 dollars)

Figure 1. The price of the Ford Model T from 1909-1923[2].

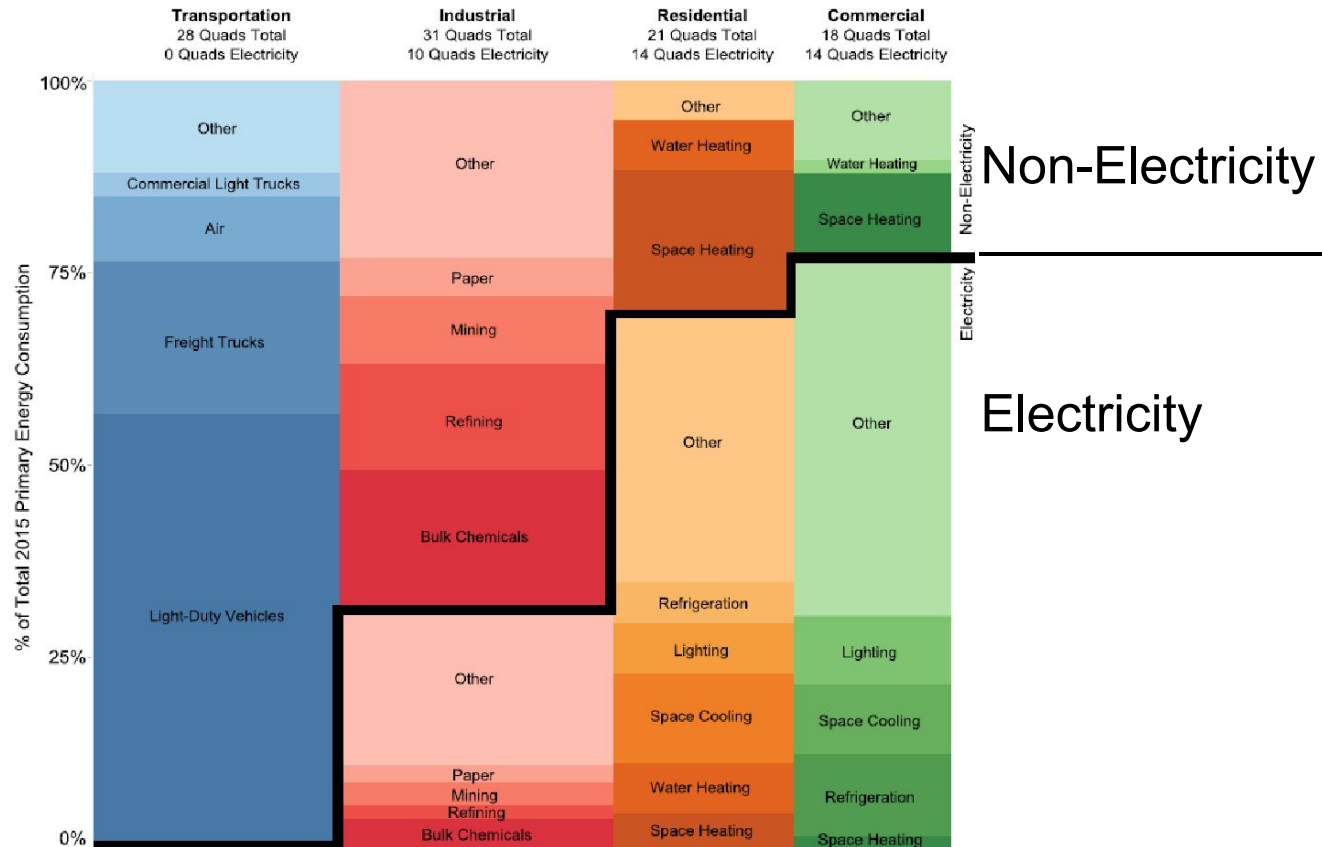

Steps toward decarbonization

Pillars of clean energy

Roles for the pillars of clean energy:

- **Efficiency:** Shrinks all boxes
- **Clean electricity:** Cleans up area below the electric frontier
- **Electrification:** Moves up the electric frontier
- **Other clean fuels:** Decarbonizes above frontier
- **Carbon sinks:** Offset the emissions that remain

Decarbonizing Electricity: Options

All renewables and nuclear have far lower life cycle emissions than any fossil fuel

Wind and solar are least cost

Levelized Cost of Energy Comparison—Unsubsidized Analysis

Selected renewable energy generation technologies are cost-competitive with conventional generation technologies under certain circumstances

Source: Lazard estimates.

Note: Here and throughout this presentation, unless otherwise indicated, the analysis assumes 60% debt at 8% interest rate and 40% equity at 12% cost. Please see page titled "Levelized Cost of Energy Comparison—Sensitivity to Cost of Capital" for cost of capital sensitivities. These results are not intended to represent any particular geography. Please see page titled "Solar PV versus Gas Peaking and Wind versus CCGT—Global Markets" for regional sensitivities to selected technologies.

- (1) Unless otherwise indicated herein, the low case represents a single-axis tracking system and the high case represents a fixed-tilt system.
- (2) Represents the estimated implied midpoint of the LCOE of offshore wind, assuming a capital cost range of approximately \$2,500 – \$3,600/kW.
- (3) The fuel cost assumption for Lazard's global, unsubsidized analysis for gas-fired generation resources is \$3.45/MMBTU.
- (4) Unless otherwise indicated, the analysis herein does not reflect decommissioning costs, ongoing maintenance-related capital expenditures or the potential economic impacts of federal loan guarantees or other subsidies.
- (5) Represents the midpoint of the marginal cost of operating fully depreciated gas combined cycle, coal and nuclear facilities, inclusive of decommissioning costs for nuclear facilities. Analysis assumes that the salvage value for a decommissioned gas combined cycle or coal asset is equivalent to its decommissioning and site restoration costs. Inputs are derived from a benchmark of operating gas combined cycle, coal and nuclear assets across the U.S. Capacity factors, fuel, variable and fixed operating expenses are based on upper- and lower-quartile estimates derived from Lazard's research. Please see page titled "Levelized Cost of Energy Comparison—Renewable Energy versus Marginal Cost of Selected Existing Conventional Generation" for additional details.
- (6) High end incorporates 90% carbon capture and storage. Does not include cost of transportation and storage.
- (7) Represents the LCOE of the observed high case gas combined cycle inputs using a 20% blend of "Blue" hydrogen, (i.e., hydrogen produced from a steam-methane reformer, using natural gas as a feedstock, and sequestering the resulting CO₂ in a nearby saline aquifer). No plant modifications are assumed beyond a 2% adjustment to the plant's heat rate. The corresponding fuel cost is \$5.20/MMBTU, assuming \$1.39/kg for Blue hydrogen.
- (8) Represents the LCOE of the observed high case gas combined cycle inputs using a 20% blend of "Green" hydrogen, (i.e., hydrogen produced from an electrolyzer powered by a mix of wind and solar generation and stored in a nearby salt cavern). No plant modifications are assumed beyond a 2% adjustment to the plant's heat rate. The corresponding fuel cost is \$10.05/MMBTU, assuming \$4.15/kg for Green hydrogen.

Wind costs have fallen 72%, and solar 90% since 2009

Levelized Cost of Energy Comparison—Historical Renewable Energy LCOE Declines

In light of material declines in the pricing of system components and improvements in efficiency, among other factors, wind and utility-scale solar PV have exhibited dramatic LCOE declines; however, as these industries have matured, the rates of decline have diminished

Unsubsidized Wind LCOE

Unsubsidized Solar PV LCOE

Source: Lazard estimates.

- (1) Represents the average percentage decrease of the high end and low end of the LCOE range.
- (2) Represents the average compounded annual rate of decline of the high end and low end of the LCOE range.

Wind and solar costs down, nuclear and coal up since 2009

Levelized Cost of Energy Comparison—Historical Utility-Scale Generation Comparison

Lazard's unsubsidized LCOE analysis indicates significant historical cost declines for utility-scale renewable energy generation technologies driven by, among other factors, decreasing capital costs, improving technologies and increased competition

Selected Historical Mean Unsubsidized LCOE Values⁽¹⁾

Nuclear +33%

Coal +1%

Wind -70%

Solar PV -90%

LAZARD Source: Lazard estimates. (1) Reflects the average of the high and low LCOE for each respective technology in each respective year. Percentages represent the total decrease in the average LCOE since Lazard's LCOE—Version 3.0.

This study has been prepared by Lazard for general informational purposes only, and it is not intended to be, and should not be construed as, financial or other advice. No part of this material may be copied, photocopied or duplicated in any form by any means or redistributed without the prior consent of Lazard.

Lithium-ion battery costs

Battery pack price (real 2020 \$/kWh)

Note: Pack price across passenger EVs, e-buses, commercial EVs and stationary storage. In EVs, the pack consists of cells, module housing, battery management system (BMS), wiring, pack housing and thermal management system. For stationary storage, we consider the equivalent to be the battery rack.

BloombergNEF

2014: Renewables, nuclear, and carbon capture pathways all seemed plausible

Figure 29. 2050 Electric Generation by Resource Type

2020: Solar and wind lead in all net-zero pathways

Solar and wind generated electricity have dominant roles in all net-zero pathways

- Share of electricity from carbon-free sources roughly doubles from ~37% today to 70-85% by 2030 and reaches 98-100% by 2050.
- Wind + solar grows >4x by 2030 to supply ~1/2 of U.S. electricity in all cases except E+RE-; in that case, growth is constrained, but still triples by 2030 to supply 1/3 of electricity.
- By 2050, wind and solar supply ~85-90% of generation in E+, E-, and E-B+. In E+RE-, 44%; in E+RE+, 98%.

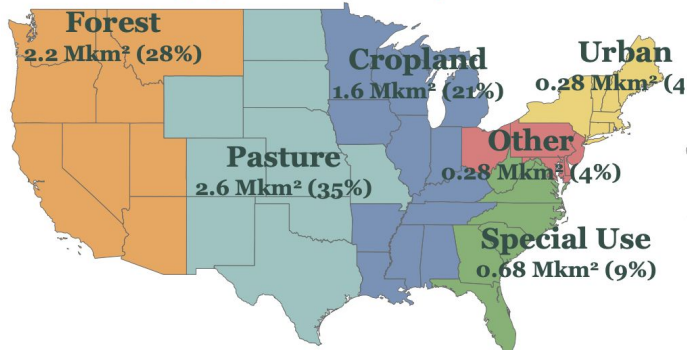

[RETURN TO TABLE OF CONTENTS](#)

Land Use for Solar, Wind, and Biomass in net-zero scenarios

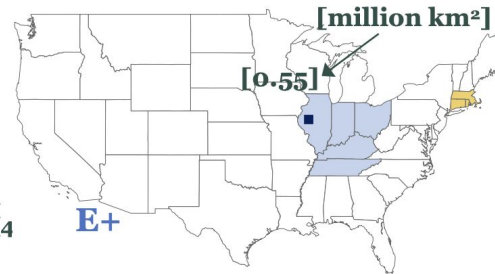

Total land area/visual footprint in 2050 for solar, wind, and biomass across scenarios is 0.25 to 1.1 million km².

**U.S. land use today, Lower-48
(7.7 Million km²)**

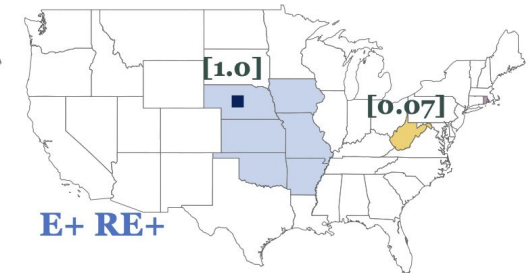

Note: In these maps, the sum of land areas of colored states is roughly the same as the area nationally of the indicated uses.

Equivalent land area for

- Solar farms
- Wind farms
- Biomass farms*
- Direct air capture

Note: Directly impacted land area for wind farms (equipment footprint) is indicated by ■. For solar and biomass, directly impacted areas are 92% and 100% of shaded area shown.

* On lands converted from food production.

CLIMATE CHANGE

What it will take to unleash the potential of geothermal power

Four new pilot plants funded by the US infrastructure bill could help expand the range of the "forgotten renewable."

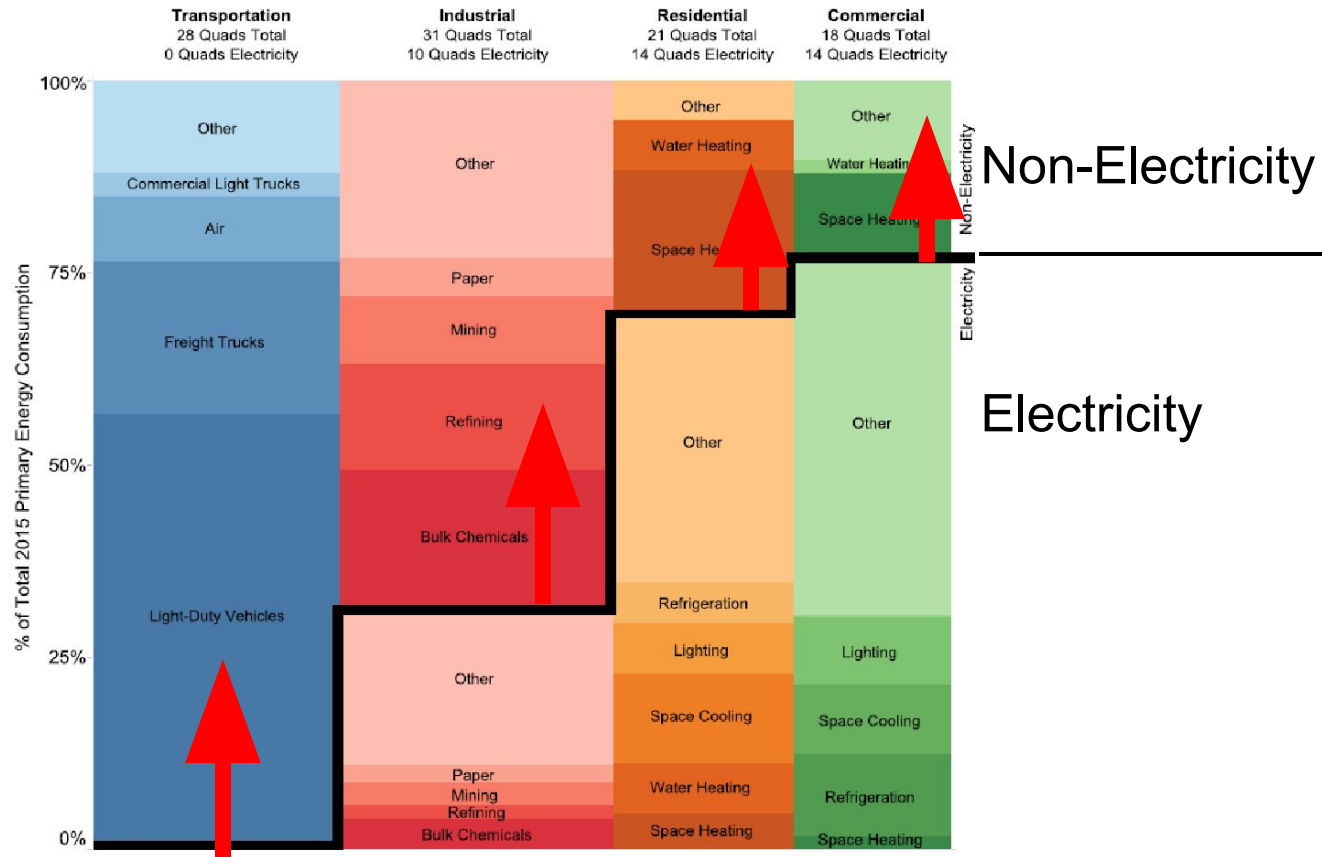

Deep Energy and Eavor forms partnership to deploy closed-loop geothermal technology

Criterion Energy Partners secures strategic investment for geothermal project

Electrification: Shifting the electric frontier

Roles for the pillars of clean energy:

- **Efficiency:** Shrinks all boxes
- **Clean electricity:** Cleans up area below the electric frontier
- **Electrification:** Moves up the electric frontier
- **Other clean fuels:** Decarbonizes above frontier
- **Carbon sinks:** Offset the emissions that remain

How homes are heated in U.S.

Mostly electricity in the South (~60% electric in Texas)

Figure 4. Natural gas is the most-used heating fuel in heated homes in three of four Census regions 
 main space heating fuel by Census region

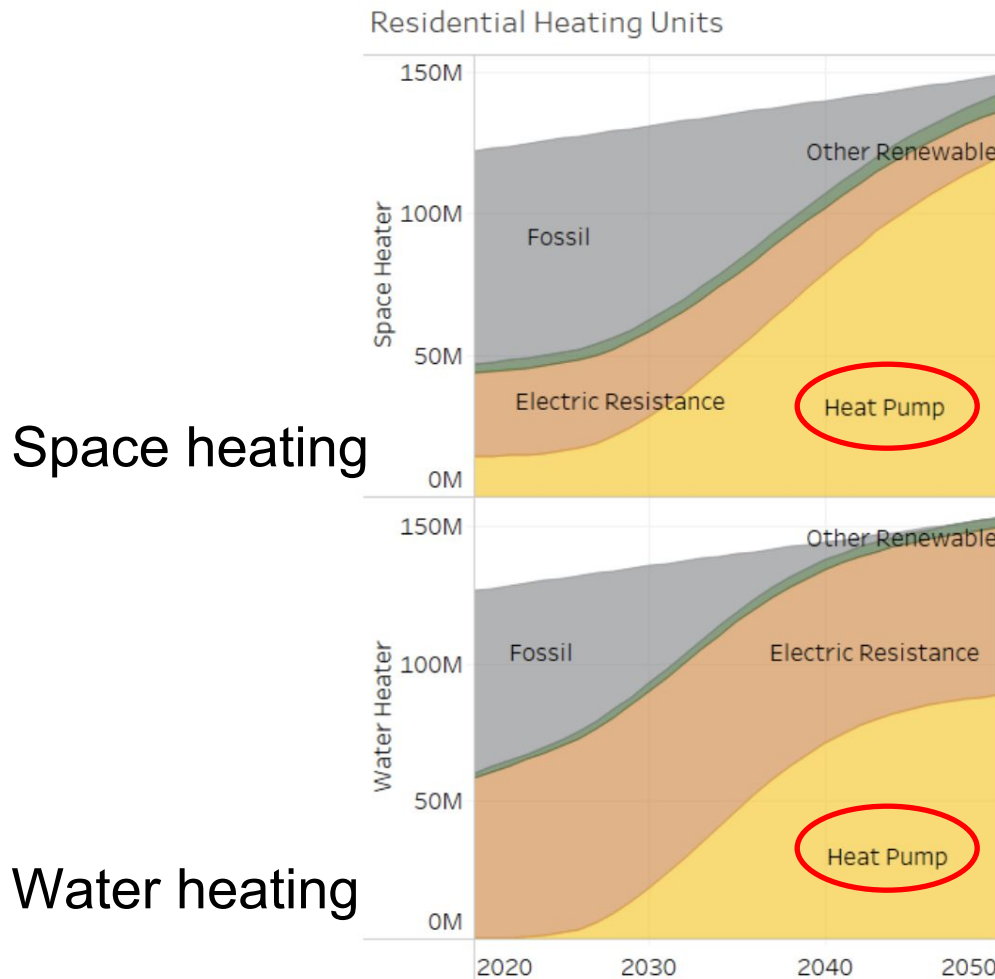

Mostly natural gas in West

Mostly natural gas and fuel oil in Northeast

Mostly natural gas in Midwest

Transition to electric heat pumps in most net-zero strategies

Policies can create virtuous cycle of technology learning curves

- \uparrow Production \square \downarrow Cost \square \uparrow Production \square
- “Technology push” policies: RD&D lowers cost of a technology (\downarrow Cost)
- “Market pull” policies: Create demand for a product (\uparrow Production)
 - Procurement: e.g., Government fleet
 - Incentives: e.g., electric car tax credits
 - Mandates: e.g., California new home solar
 - Emissions taxes

Take-home messages

- Decarbonizing the U.S. is necessary but not sufficient for decarbonization globally
- Efficiency, clean electricity, and electrification are pillars of clean energy
- Solar, wind, EVs, and heat pumps likely to lead the way
- Need to create virtuous cycles of learning by doing to drive technologies forward
